However, most papers tend to focus on either the economic or behavioral/medical factors. As suicide is likely governed by multiple factors, we seek to investigate this problem through a more holistic approach by simultaneously analyzing both

medical, behavioral, and economic factors. Through this application of machine learning, we hope to gain insight on the relative role each factor plays in suicide and about the interaction of these factors.

Moreover, most papers perform a time series analysis. We provide a different approach by analyzing the data by country. Papers that do focus on certain regions usually provide analyses on one country or a specific region, whereas we will analyze global statistics.

4 Problem Formulation and Data Set

TODO: talk about cleaning (Pandas, Excel)

4.1 Data Processing Needed

Our data came in a variety of comma-separated formats. A lot of countries were labelled in differing manner and years were often a column and other times a point in a row. We used Excel Pivot Tables to make these more easily parsable and standardized. Later, blanks and other issues with inconsistencies are removed with Python to get an aggregated set of data. Other pre-processing includes removing blanks, reconciling some country names such as (Trinidad & Tobago vs. Trinidad and Tobago).

4.2 Inputs, Outputs

Inputs are a variety of real-valued data points tied to the country. They are described above, but it remains to see which we might have to throw out due to excessive blanks. Most are also measured for a specific year, however some are just duplicated across all years (e.g. Alcohol Consumption). Outputs are a model, which given a countries characteristic features, can predict suicide rates. We have suicide rates by gender (as well as age demographics), so we may also seek a model which predicts a rate for male suicides and a rate for female suicides.

4.3 Performance Measures

Given the regression nature of this problem, we believe a squared loss model is appropriate. However, during the course of our work, we may seek alternate loss models such as a proxy

for TPR and TNR through some acceptable error window.

TODO: address her comments

5 Solution Methods and Algorithms

TODO: update to what we actually did - why we choose, how they were implemented, what languages

5.1 Algorithms Planned For Use

We will start with least squares regression in unregularized, L_1 regularized, and L_2 regularized forms. We are not certain whether any of our features will be overly correlated so the unregularized least squares regression may fail. We also seek to explore Nearest Neighbor methods, but not with vanilla Euclidean distance, but with feature weighted scaling on the distances. Lastly, we will consider using decision stubs as features and feeding the transformed input space into another learning model, perhaps Neural Nets.

5.2 Justification

As a regression problem, squared loss makes sense as a first choice. Furthermore, we want to limit ourselves to models which actually inform us about the relative importance of features. As such, vanilla nearest neighbors is not informative in the context of our problem. However, determining similarity in which features best informs Nearest Neighbors makes sense given our problem motivation.

6 Experimental Design and Results

6.1 Experiments

TODO Describe how you set up your experiments, including choice of training/testing data, choice of parameters, etc, in a way that your results can be reproduced

6.2 Results

TODO training/testing times, possible visualizations of results including both examples of good performance and examples of what types of errors are made, etc.

7 Discussion and Reflections

TODO: A LOT OF GOOD STUFF IN MESSENGER
TODO

8 Acknowledgements

TODO N/A
